

Chargehand

The general contractor for AI agents.

One budget. It hires APIs, agents, and people.

SHAPE OF THE 3 MINUTES

0:00 Hook – AI can't buy anything

0:25 DEMO – one task, one budget

1:50 What's real

2:15 The market + the money

2:40 Close

It's a money problem wearing a technology costume.

Best line in the deck. Use it early, use it once.

0 : 0 0

HOOK

“AI can think. It can’t buy anything.”

“Every tool your agent can reach, a human wired up in advance — signed up, got a key, put a card on file.”

“That’s the ceiling on agents. Not intelligence. Purchasing.”

It’s a money problem wearing a technology costume.

Straight into the demo. The graph is already moving — do not explain the graph.

► Graph already live on screen. Don't narrate it.

“One task. One five-dollar budget.

Nothing pre-wired.”

► Task: "How many people are at Ship Night right now?" Run.

1. plan posted – 5 steps
2. buys event lookup \$0.04
3. no API can see this room → hires a HUMAN \$1.50
4. refuses over-budget vision seller
5. hires the cheap one \$0.40
6. answer + receipt

The human beat

► Phone buzzes. Someone in the room shoots it. Delivers. Paid.

“No API on earth can see inside this room. So it hired a person — and paid them a dollar fifty, per unit of work, no contract.”

The budget beat

► Agent refuses the expensive seller.

“It just turned down a seller it couldn’t afford. That’s enforced in code, not in a prompt — the agent cannot talk its way past the cap.”

A market clearing in real time. Not a script.

- **72 live providers** federated from Pay.sh — Solana Foundation + Google Cloud's catalog, as supply
- **Budget enforced in code** — not a prompt instruction
- **402 job flow + human hire** — real end to end
- **Settlement is simulated tonight.** x402 V2 SVM is specced exactly — TransferChecked + memo, self-facilitated.

“Moving a dollar on Solana is the part we know how to do. Deciding *who* to pay, refusing what you can’t afford, and hiring a human when software runs out — that’s the part nobody has built.”

Volunteering this costs you 8 seconds. Getting caught on it costs you the room.

2 : 15

THE MARKET AND THE MONEY

- Take rate 2–5% of marketplace volume. No invented model.
- x402: ~165M agent transactions, ~\$50M cumulative by Apr 2026 — Solana about half
- New supply side: a solo dev lists a capability and earns from customers who are *software*

“Pay.sh is a catalog — it tells an agent what exists. A market has routing, reputation, refunds, budget policy, and human sellers. We federate their supply and build the layer above it.”

2 : 40

CLOSE

► Point at the receipt: every worker listed, one of them human.

“No contracts. No API keys. No accounts.”

Agents can’t get bank accounts. And they never will.

Ask: sellers to list, and agent teams to route through us.

THE QUESTION YOU WILL GET

"So no money actually moved?"

→ Correct — tonight signatures are mocked. Routing, the budget cap, the 402 flow, the human hire, and the Pay.sh federation are all real.

→ The settlement is specced to x402 V2's SVM scheme: three headers, TransferChecked plus a memo for replay protection, self-facilitated so there's no third party. It's about a hundred lines and it's written down.

→ We spent the night on the part that isn't solved. Payments are.

Say it flat and move on. Don't over-explain, don't apologize twice, don't let it eat your Q&A.

If you wire real devnet settlement before you pitch, **delete this page** and put "real USDC on devnet, here's the explorer link" on the What's Real page instead. It is the highest-value hour you have left.

REBUTTALS

Isn't this just Pay.sh?

→ Pay.sh is a catalog — what exists, at what price. A market adds routing, reputation, refund-on-failure, budget policy, and human supply. We federate their 72 providers rather than compete with them.

Isn't this just x402?

→ x402 is the handshake, not the marketplace. It's the rail. Rails commoditize; the trust layer on top keeps its margin.

Why not give the agent a credit card?

→ Cards can't process a third of a cent — the fee exceeds the charge. And no bank issues an account to software.

Why does this need a chain at all?

→ Software has to hold money and pay other software, in fractions of a cent, instantly, with no account relationship. Nothing else does all four.

What stops sellers returning garbage?

→ Reputation from transaction history and escrow with refund-on-failure — 30-day roadmap. Tonight the budget cap is the guard.

Prompt injection from seller responses?

→ Seller output is treated as untrusted data, never as instructions. Schema-validated, sandboxed.

Cold start — where's the supply?

→ 72 providers on night one, federated. The supply problem is the one we didn't have to solve.

The human step is slow.

→ It's the path for what no API can do. The alternative isn't faster — it's the task failing.

Stripe, Coinbase, Visa are all shipping this.

→ They're shipping rails. Rails commoditize. The market and the reputation layer is a different business — and it's only earnable over transaction history.

Is the head count real?

→ Real vision model if the key's live, otherwise a stated mock. Know which mode you're in before you walk up — don't guess on stage.

IF SOMETHING BREAKS

Worker phone / camera fails

→ "Use last capture" button. Take the backup photo BEFORE you go up.

Human step hangs

→ AUTO_PHOTO_MS auto-continues. Let it. Keep talking.

Judge types their own task

→ Generic research path always produces a run. Let them.

Graph stalls / SSE drops

→ Reload the big screen. The receipt is the payload, not the animation.

Don't

- Don't explain the graph — let it move behind you
- Don't say "marketplace" more than twice
- Don't demo before saying what's simulated
- Don't read the 5 steps aloud — they're on screen
- Don't let the settlement question eat Q&A. One answer, move on.

Name check: README says Chargehand, PRD says Bazaar. Pick one before you go up.
